Written in front

## Overview

This is a reverse+crypto challenge. We use SSE to achieve a famous stream cipher which is named Toyocrypt. The player needs to reverse the binary and recognize the algorithm. After that, the player needs to attack the crypto method with the algebraic attack and recover the initial status of lfsr, which is the flag.

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

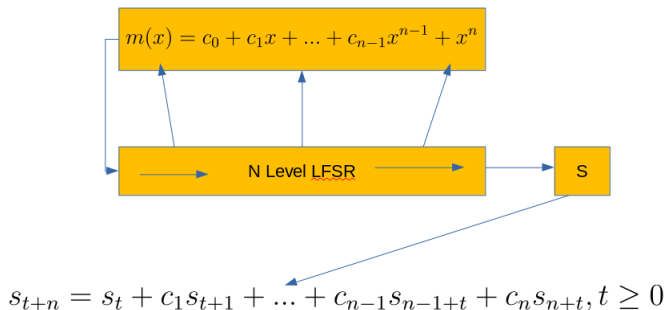

The dilemma Toy is driven from the algorithm Toyocrypt, which is a submission to the Japanese government Cryptrec call for cryptographic primitives.

To work out this problem, some simple reverse work is needed first. It can be found that we used some SSE instructions to implement a crypto algorithm. Actually, there are only two important parts of the whole process. One is LFSR function, and the other is nonlinear output combine function.

## Challenge Analysis

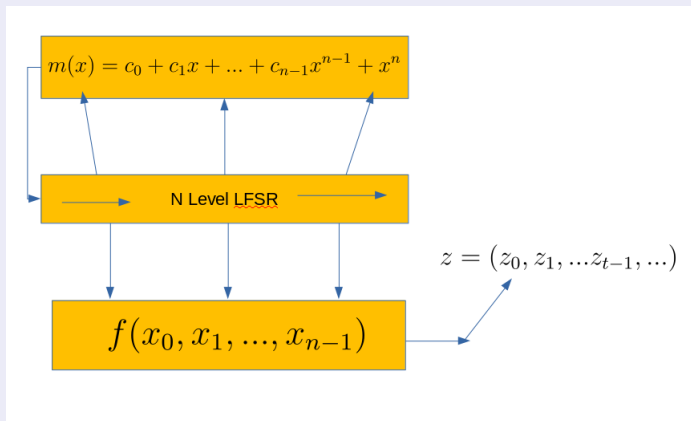

### Feedforward model based on LSRF

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

Reverse job is not very hard. SSE is interesting to achieve the Toyocrypt. Some jobs, just like xor, are easy to achieve. But some jobs, just like l-shift, are hard to achieve. After that we can see the all part of the toyocrypt with some changes.

When reverse work is done, you will find that the essence of the program is to implement a toyocrypt cryptographic algorithm with some small changes.

The original nonlinear output function is like next page:

## Challenge Analysis

But we made some changes to it.

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

But we made some changes to it. Look Like Picture!

$$f(x_0, x_1, \dots, x_{127}) = x_{127} + \sum_{i=0}^{62} x_i x_{\alpha_i} + x_{10} x_{23} x_{32} x_{42}$$

$+ \underline{x_1 x_2 x_9 x_{12} x_{18} x_{20} x_{23} x_{25} x_{26} x_{28} x_{33} x_{38} x_{41} x_{42} x_{51} x_{53} x_{59}} + \prod_{i=0}^{62} x_i$

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

Some parts of toyocrypt have been changed by us. The first part was the quaternion in the feedforward function.

We changed it from  $x_{10} * x_{23} * x_{32} * x_{42}$  to  $x_{11} * x_{22} * x_{33} * x_{53}$ .

So when we attack, we can't Directly use the existing attack methods of toyocrypt without understanding them. The second part that has been changed was the '&' in the quadratic term which is changed to ".

By doing this we reduce all of the cubic term in the algebraic attack In this way, the player can solve the problem with his personal notebook without consuming a lot of computing resources.

$$f(x_0, x_1, \dots, x_{127}) = x_{127} + \sum_{i=0}^{62} \boxed{x_i x_{a_i}} + \boxed{x_{10} x_{23} x_{32} x_{42}}$$

$+ \underbrace{x_1 x_2 x_9 x_{12} x_{18} x_{20} x_{23} x_{25} x_{26} x_{28} x_{33} x_{38} x_{41} x_{42} x_{51} x_{53} x_{59}} + \prod_{i=0}^{62} x_i$

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

To workout the initial state, we need to crack this algorithm. The two mainly ways to crack the stream cipher is algebraic attack and correlation attack.

Correlation attack is a powerful attack method on many stream ciphers, just like A5-1, and so on. However, in this algorithm, it can't be cracked by correlation attack. So, to crack this cipher, we need implement the algebraic Attack.

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

First, let's look at the original feedforward function. If we multiply an annihilator, the high order terms in the equation will be reduced to 0.

The annihilator could be  $x_{23} - 1$  or  $x_{42} - 1$ .

So, each outputbit can generate 2 equations like these. And these equations' highest order is 3.

To achieve the attack, first we need to compute the annihilators. Because of the quaternion is  $x_{11} * x_{22} * x_{33} * x_{53}$ , so the annihilators are  $(x_{33} - 1)$  and  $(x_{53} - 1)$ .

$$f(s_0, \dots, s_{127}) = s_{127} + \sum_{i=0}^{62} s_{\alpha_i} s_i + s_{10} s_{23} s_{32} s_{42} + s_1 s_2 s_9 s_{12} s_{18} s_{20} s_{23} s_{25} s_{26} s_{28} s_{33} s_{38} s_{41} s_{42} s_{51} s_{53} s_{59} + \prod_{i=0}^{62} s_i$$

The picture  $S = x$

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

### Algebraic attack: original

In the equation, the left and right sides are multiplied by the annihilator at the same time. The equation will be converted into the following form

Annihilator:  $(x_{23} - 1)$  or  $(x_{42} - 1)$

$$f(x_0, x_1, \dots, x_{127}) = x_{127} + \sum_{i=0}^{62} x_i x_{a_i} + x_{10} x_{23} x_{32} x_{42} \\ + x_1 x_2 x_9 x_{12} x_{18} x_{20} x_{23} x_{25} x_{26} x_{28} x_{33} x_{38} x_{41} x_{42} x_{51} x_{53} x_{59} + \prod_{i=0}^{62} x_i$$

$$(x_{23} - 1) * outputbit = x_{127} * (x_{23} - 1) + \sum (x_i * x_{a_i} * (x_{23} - 1)), i = \\ range(0, 63)$$

$$(x_{42} - 1) * outputbit = x_{127} * (x_{42} - 1) + \sum (x_i * x_{a_i} * (x_{23} - 1)), i = \\ range(0, 63)$$

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

### Algebraic attack: original

$$128 : 0 - X_{128}$$

$$C(128, 2) : x_i x_j$$

$$C(128, 3) : x_i x_j x_k$$

$$128 + C(128, 2) + C(128, 3) = 349623$$

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

### Tips1

```
s[i]=sum(Init_status & magic[i])
```

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

### Tips2

Each bitmap can be computed from 128 bitmaps before and the polyprim.

```
mask = 0xb64e4d3fa8e7331bd871fa30d46d4dba
magic = []
tmp = (1 << 128)
for i in range(128):
    tmp = tmp >> 1
    magic.append(tmp)
controller=bin(mask)[2:]
for i in range(128, 8256):
    i_magic = 0
    for point in range(128):
        if controller[point]=='1':
            i_magic ^= magic[i-128+point]
    magic.append(i_magic)
```

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

In algebraic attack, we need to do Gauss elimination. But there are quadratic terms here. So we define all quadratic terms as new unknown vars.

```
ttable = []
for i in range(128):
    tmp=[]
    for j in range(128):
        tmp.append(-1)
    ttable.append(tmp)
point = 128
for i in range(127):
    for j in range(i + 1, 128):
        ttable[i][j] = point
        ttable[j][i] = point
        point += 1
alreadylist=[]
for i in range(128):
    for j in range(128):
        assert ttable[i][j]==ttable[j][i]
        assert ttable[i][j]<8256
        if ttable[i][j] not in alreadylist and ttable[i][j]!=-1:
            alreadylist.append(ttable[i][j])
assert len(alreadylist)==8256-128
for i in range(128):
    assert ttable[i][i]==-1
```

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

Thus there are  $128 + C(128, 2)$  unknown vars. One output bit can generate 2 equations by 2 annihilators. So 8256 bit is enough to finish the attack. Finally, we list all the equations and use Gauss elimination to restore the initial state of the register.

## Challenge Analysis

Gaussian elimination results out the first 128 bits is the flag!

[illegible]

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

### Why we put out this problem?

There are many crypto problems in former CTFs. However, algebraic attack is so important in cryptography, so we think we need put out a problem about algebraic attack to help the competitors to learn this attack method.

# WCTF 2019 Challenge Toy Solution

## Challenge Analysis

By work out this problem, what can you get?

Knowing the standard algebraic attack process. Knowing the way to work out annihilator. Knowing the way to simplify the attack process for algebraic attack by XL ( eXtended Linearizations) method.

The End!  
Thanks!
